Homework 2 Com S 311

Due: Sep 11, 11:59PM Total Points: 100

Late submission policy. If you submit by Sept 12, 11:59PM, there will be 20% penalty. That is, if your score is x points, then your final score for this homework after the penalty will be $0.8 \times x$. Submission after Sept 12, 11:59PM will not be graded without explicit permission from the instructors.

Submission format. Your submission should be in pdf format. Name your submission file: <Your-net-id-stl-test part. For instance, flypur netid is asterix, then your submission file will be named asterix-311-hw2.pdf.

Rules for Algorithm-design Problems.

- 1. For all algorithm design problems, part of the grade depends on the run-time. Better the run-time, higher the grade.
- 2. You may use Heap operations such as BuildHeap, HeapifyUp, heapifyDown, add, delete, extractMin/Max in your solutions without describing the procedure.
- 3. Similarly you can use hash table operations such as build Hash table, add, delete, search without describing them.

Learning outcomes.

- 1. Determine whether or not a function is Big-O of another function
- 2. Analyze asymptotic worst-case time complexity of algorithms
- 3. Design algorithms (including using Heap and/or Hash-Table)

1. Prove or disprove the following statements.

(20 Points)

```
(a) 2^{2n} \in O(2^n)
```

(b)
$$f_1(n) \in O(g_1(n)) \land f_2(n) \in O(g_2(n)) \Rightarrow f_1(n) \times f_2(n) \in O(g_1(n) \times g_2(n))$$

Ans. Not provided. Please see TA/instructor in office hours

2. Derive runtime for (20 Points)

```
(a) for i in the range [1, n-1]
    for j in the range [i, n]
    for k in the range [1, j]
        do-something-atomic
```

Ans. Not provided. Please see TA/instructor in office hours

```
(b) i=0
    j=n
    while (i<=j)
    while (a[i] < k) i++;
    while (a[j] > k) j--;
```

Assignment Project Exam Help

```
a[i] = a[j];
a[j] = t
```

https://eduassistpro.github.io/g each iteration, at least one of the following must happen: i) i is incremented, ii) j is decremented, iii) a[i] is swapped in a[j]. Let x = a[i] and y = 0 on i) and ii) do not happen. This is because x = a[i] and y = 0 on i) and ii) performed, we have that a[i] = y and a[j] = x. Sin 0 < k, thus in the next iteration, i must be incremented, and similarly since x > k and a[j] = x, in the next iteration, j must be decremented. Thus every time a swap operation is performed, i is incremented or i is decremented (or both could happen). Since i can be incremented at most i times and i can be decremented at most i times, we can conclude that the swap operation is performed at most i times. Thus the total number of operations are bounded by number of times i is incremented, plus number of times i is decremented plus number of times swap operation is performed. Time taken to increment i, decrement i and swap is a constant. Thus the total time can be at most i (Time to increment i) i and swap is a constant. Thus the total time can be at most i (Time to increment i) i and swap is a constant. Thus the total time can be at most i (Time to increment i) i and swap is a constant. Thus the total time can be at most i (Time to increment i) i and swap is a constant.

3. Design algorithms for the following problems

- (60 Points)
- (a) Given a sorted array A of integers and an integer T, the goal is to determine if there exists two numbers in the array that sum to T. Write an algorithm that takes A as input and outputs true or false. You are not allowed to use hash-tables in this algorithm. Derive the runtime of your algorithm.

Ans. Consider the following algorithm.

```
Input: Array a, Integer T.
left = 1;
right = length of the array;
while (left <=right){
    x = a[left] + a[right];
    if (x==T)
        return true;
    if (x < T)
        left++;
    if (x > T)
        right--;
}
```

return false;

Rantime: Consider an iteration of the while toop. One of the following three will happen sleep introducted by one of the while the popular of the will be a second that I by the loop quits. The worst-case time when the loop does not quit because x is never equal to T. So we consider this

(b) Given an array A consisting of integers, the *goal* is to construct a two-dimensional array B such that $B[i,j] = \sum_{k=i}^{k=j} A[k]$. Write an algorithm that takes A as input and outputs B. Derive the runtime of your algorithm.

Ans. Consider the following algorithm.

```
for i from 1 to n-1 do D[i,i+1] \leftarrow a[i] + a[i+1] for j from i+2 to n do D[i,j] \leftarrow D[i,j-1] + a[j] end for end for
```

Correctness: D[i, i+1] = a[i] + a[i+1], as it should. Assuming that $D[i, j-1] = \sum_{k=i}^{j-1} a[k]$, the algorithm will set D[i, j] to $\sum_{k=i}^{j-1} a[k] + a[j] = \sum_{k=i}^{j} a[k]$.

Runtime: The innermost for loop runs n-i-1 times, and each time it performs two constant-time operations. Call the time taken by them c. The outermost for loop

performs another constant-time operation taking d time, before entering the inner loop. The total time is thus given by the sum

$$\sum_{i=1}^{n-1} \left(d + \sum_{j=i+1}^{n} c \right)$$

Again, we break up the inner sum into $\sum_{j=1}^{n} c - \sum_{j=1}^{i} c$, which simplifies to nc - ic. The outer sum is thus

$$\sum_{i=1}^{n-1} (d + nc - ic)$$

$$= (n-1)d + (n-1)nc - \frac{(n-1)n}{2}c$$

$$= (n-1)d + \frac{(n-1)n}{2}c$$

$$\in O(n^2)$$

(c) Given an array A containing 0s and 1s, such that all the 0s appear in the array before all the STAGA IS THE THE STAGA IS THE STAGA IS

Ans. We m

i. left = https://eduassistpro.github.io/

- $mid = \frac{left + right}{/}2$. If A[nid] = 1 and a[mid 1] = 1, redu_assist_pro

 - if A[mid] = 0, left = mid.
- iii. Return false.

Runtime. The worst-case time is when the loop does not terminate because, it found mid. At the start of an iteration let x be the value of left and y be the value of right. Thus right - left = y - x. After the iteration, there are two possibilities: $right = \frac{x+y}{2}$ or $left = \frac{x+y}{2}$. In both cases right - left is (y-x)/2. Thus after each iteration, the difference between right and left is halved. Initial difference between them is n. Thus after $O(\log n)$ iterations, left will be higher than right and the loop terminates. Each iteration of the loop takes O(1) time, thus the time is $O(\log n)$.

(d) A binary Heap is implemented using array. There are several standard operations that are defined over such a heap structure:

getMin: parameters include array. Runtime: O(1).

add: parameters include array, value of the element being added, the number of elements in the heap. Runtime: $O(\log n)$

delete: parameters include array, index of the element being deleted, the number of elements in the heap. Runtime $O(\log n)$

Notice that the **delete** operations allows you to delete element at a specific index. The goal is add a new operation deleteValue(x), where the parameter x denotes the value of the element(s) that needs to be deleted from the heap, and ensure that the operation can be done in expected $O(\log n)$ time, where n is the number of elements in the heap. Augment of the heap structure (i.e., add additional information/property to the heap structure) which will allow you to design the algorithm for deleteValue(x) with spec-

If your augmentation of the heap structure requires changes in the way the existing standard operations are implemented, then you need to mention those changes.

ified runtime, without altering the runtime for the rest of the standard operations.

Ans. We will augment the basic heap data structure H with a hash table T, consisting of $\langle key, value \rangle$ pairs, while maintaining the following property: If H[i] = v if and only if $\langle v, i \rangle$ belongs to T. We also maintain a counter to indicate the number of elements stored in the heap. Note that we can do operations such as add(key), delete(key) and search(key) operations on the hash table in expected O(1) time. Modify the search(key) method so that it returns i such that $\langle key, i \rangle \in T$. If there is no such i, then this method returns -1. Note that this modified method can also be done in expected O(1) time.

We now modify the HeapifyUp and HeapifyDown operations of the heap so that the above mentioned property is maintained. We describe HeapifyUp(i,y): The goal of the method is to replace H[i] with y (if y < H[i]), and maintain the heap property. Set H[i] and the heap property is maintained (since y < H[1]). Let p be the index of the parent of i in the heap. Compute the minimum among H[represents the property of the theory of the property is maintained.

minimum in the profedure stops. If the mit ps://eduassistpro.g|p|, derete $\langle H[p], p \rangle$ from the hash table and add $\langle H[p], i \rangle$ to the hash table yUp(p,y). Similarly we can define HapifyDown(i,y) operation. N the profession of the dark formula of the profession of the profes

hash table. Since the hash table operations take expected O(1) time, this will increase the total time by a factor of O(1). Thus the time taken for these operations is expected $O(\log n)$ time. These operations can be used to add and element to the heap or extract minimum element from the heap.

We are now ready to describe the methods:

Add(v). Place $\langle v, counter+1 \rangle$ in T and add v to the binary heap (by using the above described methods HeapifyUp and HeapifyDown. Increment counter by 1. The time taken is $O(\log n)$.

DeleteValue(v): Call search(v), if this returns i, then remove $\langle v, i \rangle$ from the hash table and delete H[i] from the heap by using above described methods HeapifyUp and HeapifyDown. The time taken is $O(\log n)$.

min(). Returns H[1]. Time taken is O(1).

extractMin(). Remove $\langle H[1], 1 \rangle$ from the hash table. Decrement counter by 1. Perform extract Min operation on H (by using described methods HeapifyUp and HeapifyDown. Time taken is $O(\log n)$.
